

LAB 12 ALGORITHM

Randomised quick sort is an extension of quicksort in which the pivot element is chosen randomly.

```
import random

def partition(arr,l,h):
    pivot=l

    i=l-1 #initialising left index
    j=h+1 #initialising right index
    while(True):
        while(True):
            i=i+1
            if(arr[i]>=arr[pivot]):
                break
        while(True):
            j=j-1
            if(arr[j]<=arr[pivot]):
                break
        if(i>=j):
            return j
        arr[i],arr[j]=arr[j],arr[i]

    # return j

def quicksort(arr,l,h):
    if(l<h):
        j=randompivot(arr,l,h)
        quicksort(arr,l,j)
        quicksort(arr,j+1,h)

def randompivot(arr,l,h):
    rpivot=random.randrange(l,h)
    print("Index of pivot is:" , rpivot," , value at that index:" ,arr[rpivot])
```

```
arr[l],arr[rpivot]=arr[rpivot],arr[l]
return partition(arr,l,h)
#return quicksort(arr,l,h)

arr =[10, 5, 7, 9, 12, 17, 4, 8, 2, 11]
#randompivot(arr,0,len(arr)-1)
quicksort(arr, 0, len(arr) - 1)
print(arr)
```

Explanation:

In this case, the pivot has been selected by using the "random" function. First, the index position 6 with value 4 has been chosen as the index.

So, the first element i.e. 10 is swapped with 4. So the new array now is [4, 5, 7, 9, 12, 17, 10, 8, 2, 11].

Now the value of arr[i] is 4 and arr[j] is 11. Now, as i moves ahead in one iteration, j also moves to 2.

Now, 5 and 2 are swapped. Now, the process is continued until j crosses i. In quicksort, the new position

of j is swapped with the pivot element. Now, the next pivot element is 7 and the same process is repeated.
